Current trials are examining the efficacy of intravenous vitamin C as cancer therapy. The present review outlines the differences in vitamin C pharmacokinetics compared to normal low molecular weight drugs, focusses on potential pitfalls in study design and data interpretation, and re-examines major clinical studies of vitamin C in light of these. Having both specific and unspecific biological functions, it has been widely accepted as Go to Introduction. Thus, when reexamining the clinical literature on vitamin C, one is left with little certainty and many questions, including those presented in the introduction: What is the optimal intake of vitamin C and what is its preventive and therapeutic potential? Vitamin C is a water-soluble compound found in living organisms. Vitamin C is a ubiquitous water-soluble electron donor in living organisms and an essential nutrient in man. Vitamin C is an essential dietary nutrient for the biosynthesis of collagen and a co-factor in the biosynthesis of catecholamines, L-carnitine, cholesterol, amino acids, and some peptide. The various functions of vitamin C, including the antioxidant activity, formation of protein, tendons, ligaments and blood vessels, for healing wounds and form scar tissue, for repair-ing and maintaining cartilage, bone, and teeth, and aiding in the absorption of iron, were discussed.
